Abstract

We study a sequential resource allocation problem involving a fixed number of recurring jobs. At each time-step the manager should distribute available resources among the jobs in order to maximise the expected number of completed jobs. Allocating more resources to a given job increases the probability that it completes, but with a cut-off. Specifically, we assume a linear model where the probability increases linearly until it equals one, after which allocating additional resources is wasteful. We assume the difficulty of each job is unknown and present the first algorithm for this problem and prove upper and lower bounds on its regret. Despite its apparent simplicity, the problem has a rich structure: we show that an appropriate optimistic algorithm can improve its learning speed dramatically beyond the results one normally expects for similar problems as the problem becomes resource-laden.

1 INTRODUCTION

Assume that there are $K$ jobs and at each time-step $t$ a learner must distribute the available resources with $M_{k,t} \geq 0$ going to job $k$, subject to a budget constraint,

$$\sum_{k=1}^{K} M_{k,t} \leq 1.$$ 

The probability that the $k$th job completes in time-step $t$ is $\min \{1, M_{k,t}/\nu_k\}$, where the unknown cut-off parameter $\nu_k \in (0, \infty]$ determines the difficulty of job $k$. After every time-step the resources are replenished and all jobs are restarted regardless of whether or not they completed successfully in the previous time-step. The goal of the learner is to maximise the expected number of jobs that successfully complete up to some known time horizon $n$.

Despite the simple model, the problem is surprisingly rich. Given its information structure, the problem belongs to the class of stochastic partial monitoring problems, which was first studied by Agrawal et al. [1989][1], where in each time step the learner receives noisy information about a hidden “parameter” while trying to maximise the sum of rewards and both the information received and the rewards depend in a known fashion on the actions and the hidden parameter. While partial monitoring by now is relatively well understood, either in the stochastic or the adversarial framework when the action set is finite [Bartók et al., 2011, Foster and Rakhlin, 2012, Bartók, 2013], the case of continuous action sets has received only limited attention [Broder and Ramesh, 2012, and references therein]. To illustrate the difficulty of the problem, notice that over-assigning resources to a given job means that the job completes with certainty and provides little information about the job’s difficulty. On the other hand, if resources are under-assigned, then the information received allows one to learn about the payoff associated with all possible arms, which is reminiscent of bandit problems where the arms have “correlated payoffs” (e.g., Filippi et al. 2010, Russo and Roy 2013 and the references therein). Finally, allocating less resources yields high-variance estimates.

Our motivation to study this particular framework comes from the problem of cache allocation. In particular, data collected offline from existing and experimental allocation strategies showed a relatively good fit to the above parametric model. In this problem each job is a computer process, which is successful in a given time-step if there were no cache misses (cache misses are very expensive). Besides this specific resource allocation problem, we also envision other applications, such as load balancing in networked environments, or any other computing applications where some precious resource (bandwidth, radio spectrum, CPU, etc.) is to be subdivided amongst competing processes. In fact, we anticipate numerous extensions and adaptations for

---

[1] The name was invented later by (perhaps) [Rustichini, 1999].
specific applications, such as in the case of bandits (see, Bubeck and Cesa-Bianchi [2012] for an overview of this rich literature). Finally, let us point out that although our problem is superficially similar to the so-called budgeted bandit problems (or, budget limited bandit problems), there are some major differences: in budgeted bandits, the information structure is still that of bandit problems and the resources are not replenished. Either learning stops when the budget is exhausted (e.g., Tran-Thanh et al. 2012, Ding et al. 2013, Badanidiyuru et al. 2013)

\[ \sum_{t=1}^{K} M_{k,t} = \ell + \frac{S^*}{\nu_{t+1}}. \]

The main contribution besides the introduction of a new problem is a new optimistic algorithm for this problem that is shown to suffer poly-logarithmic regret with respect to optimal omniscient algorithm that knows the parameters \((\nu_k)_{k}\) in advance. The structure of the bound depends significantly on the problem dynamics, ranging from a (relatively) easy full-information-like setting, corresponding to a resource-laden regime, to a bandit-like setting, corresponding to the resource-scarce setting. Again, to contrast this work to previous works, note that the results we obtain for the full-information-like setting are distinct from those possible in the finite action case, where the full-information setting allows one to learn with finite regret [Agrawal et al., 1989]. On the technical side, we believe that our study and use of weighted estimators in situations where some samples are more informative than others might be of independent interest, too.

Problems of allocating resources to jobs were studied in the community of architecture and operating systems. Liu et al. [2004] build static profile-based allocation of L2-cache banks to different processes using their current miss rate data. Suh et al. [2002] proposed a hit-rate optimisation using hardware counters which used a model-based estimation of hit-rate vs allocated cache. However, they all assume the model is fully known and no learning is required. Bitirgen et al. [2008] used ANNs to predict individual program performance as a function of resources. Finally, Ipek et al. [2008] used reinforcement learning to allocate DRAM to multi-processors.

2 PRELIMINARIES

In each time-step \(t\) the learner chooses \(M_{k,t} \geq 0\) subject to the constraint, \(\sum_{k=1}^{K} M_{k,t} \leq 1\). Then all jobs are executed and \(X_{k,t} \in \{0, 1\}\) indicates the success or failure of job \(k\) in time-step \(t\) and is sampled from a Bernoulli distribution with parameter \(\beta(M_{k,t}/\nu_k) := \min\{1, M_{k,t}/\nu_k\}\). The goal is to maximise the expected number of jobs that successfully complete, \(\sum_{k=1}^{K} \beta(M_{k,t}/\nu_k)\). We define the gaps \(\Delta_j, k = \nu_j^{-1} - \nu_k^{-1}\). We assume throughout for convenience, and without loss of generality, that \(\nu_1 < \nu_2 < \cdots < \nu_K\). It can be shown that the optimal allocation distributes the resources to jobs in increasing order of difficulty.

\[ M_{k}^* = \min \left\{ 1 - \sum_{i=1}^{k-1} \frac{M_{i}^*}{\nu_k} \right\}. \]

We let \(\ell\) be the number of jobs that are fully allocated under the optimal policy: \(\ell = \max\{i : M_{i}^* = \nu_i\}\). The overflow is denoted by \(S^* = M_{K+1}^*\), which we assume to vanish if \(\ell = K\). The expected reward (number of completed jobs) when following the optimal allocation is

\[ \sum_{k=1}^{K} \frac{M_{k}^*}{\nu_k} = \ell + \frac{S^*}{\nu_{K+1}}, \]

where we define \(\nu_{K+1} = \infty\) in the case that \(\ell = K\). The (expected \(n\)-step cumulative) regret of a given allocation algorithm is the difference between the expected number of jobs that complete under the optimal policy and those that complete given the algorithm,

\[ R_n = \mathbb{E} \left[ \sum_{t=1}^{n} r_t \right], \quad r_t = \sum_{k=1}^{K} \beta(M_{k,t}/\nu_k) - \sum_{k=1}^{K} \beta(M_{k,t}/\nu_k) \]

= \left( \ell + \frac{S^*}{\nu_{K+1}} \right) - \sum_{k=1}^{K} \beta(M_{k,t}/\nu_k). \]

Some proofs are omitted due to space constraints, but may be found in the supplementary material [Lattimore et al., 2014].

3 OVERVIEW OF ALGORITHM

We take inspiration from the optimal policy for known \(\nu_k\), which is to fully allocate the jobs with the smallest \(\nu_k\) (easiest jobs) and allocate the remainder/overflow to the next easiest job. At each time-step \(t\) we replace the unknown \(\nu_k\) by a high-probability lower bound \(\nu_{k,t-1} \leq \nu_k\). This corresponds to the optimistic strategy, which assumes that each job is as easy as reasonably possible. The construction of a confidence interval about \(\nu_k\) is surprisingly delicate. There are two main challenges. First, the function \(\beta(M_{k,t}/\nu_k)\) is non-differentiable at \(M_{k,t} = \nu_k\), and for \(M_{k,t} \geq \nu_k\) the job will always complete and little information is gained. This is addressed by always using a lower estimate of \(\nu_k\) in the algorithm. The second challenge is that \(M_{k,t}\) will vary with time, so the samples \(X_{k,t}\) are not identically distributed. This would normally be unproblematic, since martingale inequalities can be applied, but the specific structure of this problem means that a standard sample average estimator is a little weak in the sense that its estimation accuracy can be dramatically improved. In particular, we will propose an estimator that is able to take advantage of the fact that the
variance of \( X_{k,t} \) decreases to zero as \( M_{k,t} \) approaches \( \nu_k \) from below.

As far as the estimates are concerned, rather than estimate the parameters \( \nu_k \), it turns out that learning the reciprocal \( \nu_k^{-1} \) is both more approachable and ultimately more useful for proving regret bounds. Fix \( k \) and let \( M_{k,1}, \ldots, M_{k,t} \leq \nu_k \) be a sequence of allocations with \( M_{k,s} \leq \nu_k \) and \( X_{k,s} \sim Bernoulli(M_{k,s}/\nu_k) \). Then a natural (unbiased) estimator of \( \nu_k^{-1} \) is given by

\[
\frac{1}{\hat{\nu}_{k,t}} := \frac{1}{t} \sum_{s=1}^{t} X_{k,s} / M_{k,s}.
\]

The estimator has some interesting properties. First, the random variable \( X_{k,s}/M_{k,s} \in [0,1/M_{k,s}] \) has a large range for small \( M_{k,s} \), which makes it difficult to control the error \( \hat{\nu}_{k,t}^{-1} - \nu_k^{-1} \) via the usual Azuma/Bernstein inequalities. Secondly, if \( M_{k,s} \) is close to \( \nu_k \), then the range of \( X_{k,s}/M_{k,s} \) is small, which makes estimation easier. Additionally, the variance is greatly decreased for \( M_{k,s} \) close to \( \nu_k \). This suggests that samples for which \( M_{k,s} \) is large are more useful than those where \( M_{k,s} \) is small, which motivates the use of the weighted estimator,

\[
\frac{1}{\hat{\nu}_{k,t}} := \frac{1}{t} \sum_{s=1}^{t} \frac{w_{s} X_{k,s}}{M_{k,s}},
\]

where \( w_s \) will be chosen in a data-dependent way, but with the important characteristic that \( w_s \) is large for \( M_{k,s} \) close to \( \nu_k \). The pseudo-code of the main algorithm is shown in Algorithm Listing 1. It accepts as input the horizon \( n \), the number of jobs, and a set \( \{\nu_{k,0}\}_{k=1}^{K} \) for which \( 0 < \nu_{k,0} \leq \nu_k \) for each \( k \). In Section 7 we present a simple (and efficient) algorithm that relaxes the need for the lower bounds \( \nu_{k,0} \).

\textbf{Remark 1.} Later (in Lemma 6) we will show that with high probability \( 1 \leq w_{k,s} \leq O(s) \). By definition the confidence bounds \( \nu_{k,t} \) and \( \hat{\nu}_{k,t} \) are non-decreasing/increasing respectively. These results are sufficient to guarantee that the new algorithm is numerically stable. It is also worth noting that the running time of Algorithm 1 is \( O(1) \) per time step, since all sums can be computed incrementally.

## 4 UPPER BOUNDS ON THE REGRET

The regret of Algorithm 1 depends in a subtle way on the parameters \( \nu_k \). There are four natural cases, which will appear in our main result.

\textbf{Case 1: Insufficient budget for any jobs.} In this case \( \ell = 0 \) and the optimal algorithm allocates all available resources to the easiest task, which means \( M_{1} = 1 \). Knowing that \( \ell = 0 \), the problem can be reduced to a \( K \)-armed Bernoulli bandit by restricting the action space to \( M_{k,t} = 1 \) for all \( k \). Then a bandit algorithm such as UCB1 [Auer et al., 2002] will achieve logarithmic (problem dependent) regret with some dependence on the gaps \( \Delta_{1,k} = \frac{1}{\nu_1} - \frac{1}{\nu_k} \). In particular, the regret looks like \( R_n \in O\left(\sum_{k=2}^{K} \log n \right) \).

\textbf{Case 2: Sufficient budget for all jobs.} In this case \( \ell = K \) and the optimal policy assigns \( M_{k,t} = \nu_k \) for all \( k \), which enjoys a reward of \( K \) at each time-step. Now Algorithm 1 will choose \( M_{k,t} = \nu_{k,t-1} \) for all time-steps and by Theorem 4 stated below we will have \( \nu_{k,t-1}/\nu_k \in O(1 - \frac{1}{\ell} \log n) \). Consequently, the regret may be bounded by \( R_n \in O\left(\log^2 n \right) \) with no dependence on the gaps.

\textbf{Case 3: Sufficient budget for all but one job.} Now the algorithm must learn which jobs should be fully allocated. This introduces a weak dependence on the gaps \( \Delta_{\ell,k} \) for

### Algorithm 1 Optimistic Allocation Algorithm

1: \textbf{input:} \( n, K, \{\nu_{k,0}\}_{k=1}^{K} \)
2: \( \delta \leftarrow (nK)^{-2} \) and \( \nu_{k,0} = \infty \) for each \( k \)
3: for \( t = 1, \ldots, n \) do
4: \quad /* Optimistically choose \( \nu_{k,t} \) */
5: \quad \( \nu_{k,t} \leftarrow \nu_{k,t-1} \)
6: \quad \( \forall k \in 1, \ldots, K \) initialise \( M_{k,t} \leftarrow 0 \)
7: \quad for \( i = 1, \ldots, K \) do
8: \qquad \( M_{k,t} \leftarrow \min \{\nu_{k,t-1}, 1 - \sum_{j=1}^{K} M_{j,t}\} \)
9: \quad end for
10: \( \forall k \in 1, \ldots, K \) observe \( X_{k,t} \)
11: \( \forall k \in 1, \ldots, K \) compute weighted estimates:
12: \quad \( w_{k,t} \leftarrow \frac{1}{\nu_{k,t}} \sum_{s=1}^{t} \frac{w_{s} X_{k,s}}{M_{k,s}} \)
13: end for
14: function \( f(R, V^2, \delta) \)
15: \quad \( \delta_0 \leftarrow \frac{(R+1)^2}{(V^2) + 1} \)
16: \quad return \( \frac{R+1}{3} \log \frac{2}{\delta_0} \)
17: \quad + \sqrt{2(V^2 + 1) \log \frac{2}{\delta_0} + \left(\frac{R+1}{3}\right)^2 \log^2 \frac{2}{\delta_0} } \)
18: end function
$k > \ell$, but choosing the overflow job is trivial. Again we expect the regret to be $O(\log^2 \nu t)$, but with an additional modest dependence on the gaps.

**Case 4: General case.** In the completely general case even the choice of the overflow job is non-trivial. Ultimately it turns out that in this setting the problem decomposes into two sub-problems. Choosing the jobs to fully allocate, and choosing the overflow job. The first component is fast, since we can make use of the faster learning when fully allocating. Choosing the overflow reduces to the bandit problem as described in case 1.

Our main result is the following theorem bounding the regret of our algorithm.

**Theorem 2.** Let $\delta$ be as in the algorithm, $\eta_k = \min \{1, \nu_k\}/\nu_k$.

\[
R_n \leq 1 + \sum_{k=1}^{\ell} c_{k,1}\eta_k(1 + \log n) + \mathbb{1}\{\ell < K\} \left[ \sum_{k=\ell+2}^{K} \frac{c_{k,2}}{\nu_k \Delta_{\ell+1,k}} + \sum_{1}^{\ell} c_{k,1}\eta_k(1 + \log n) \right. \\
+ \left. \sum_{k=\ell+2}^{K} c_{k,1}\eta_k(1 + \log u_{\ell+1,k}) + \sum_{k=\ell+1}^{K} c_{k,1}\eta_k(1 + \log u_{\ell,k}) \right] .
\]

If we assume $\eta_k \in O(1)$ for each $k$ (reasonable as discussed in Section 7), then the regret bound looks like

\[
R_n \leq O\left(\ell^{\log 2} n + \sum_{k=1}^{\ell} \left( \log \frac{1}{\nu_k} \Delta_{\ell,k} \right) \log n \right)
\]

where the first term is due to the gap between $\nu_{k-1}$ and $\nu_k$, the second due to discovering which jobs should be fully allocated, while the third and fourth terms are due to mistakes when choosing the overflow job.

The proof is broken into two components. In the first part we tackle the convergence of $\hat{\nu}_{k,0}$ to $\nu_k$ and analyse the width of the confidence intervals, which are data-dependent and shrink substantially faster when $M_{k,t}$ is chosen close to $\nu_k$. In the second component we decompose the regret in terms of the width of the confidence intervals. While we avoided large constants in the algorithm itself, in the proof we focus on legibility. Optimising the constants would complicate an already long result.

### 5 Estimation

We consider a single job with parameter $\nu$ and analyse the estimator and confidence intervals used by Algorithm 1. We start by showing that the confidence intervals contain the truth with high-probability and then analyse the rate at which the intervals shrink as more data is observed. Somewhat surprisingly the rate has a strong dependence on the data with larger allocations leading to faster convergence.

Let $\mathcal{F}_t^{\infty} = \mathcal{F}_t$ be a filtration and let $M_1, \ldots, M_n$ be a sequence of positive random variables such that $M_t$ is $\mathcal{F}_{t-1}$-measurable. Define $X_t$ to be sampled from a Bernoulli distribution with parameter $\beta(M_t/\nu)$ and assume that $X_t$ is $\mathcal{F}_t$-measurable. Our goal is to construct a sequence of confidence intervals $\{[\hat{\nu}_t, \bar{\nu}_t]\}_{t=1}^n$ such that $\nu \in [\hat{\nu}_t, \bar{\nu}_t]$ with high probability and $\bar{\nu}_t - \hat{\nu}_t \to 0$ as fast as possible. We assume a known lower bound $\nu_0 \leq \nu$ and define $\bar{\nu}_0 = \infty$. Recall that the estimator used by Algorithm 1 is defined by

\[
\hat{\nu}_t = \frac{1}{t-M_t}, \quad \bar{\nu}_t = \frac{1}{\sum_{s=1}^{t} w_s M_s} \cdot \sum_{s=1}^{t} w_s X_s .
\]

Fix a number $0 < \delta < 1$ and define $\hat{\varepsilon}_t = f(R_t, \hat{V}_t, \delta)/\sum_{s=1}^{t} w_s M_s$, where the function $f$ is defined in Algorithm 1, $R_t = \max_{s \leq t} w_s$ and $\hat{V}_t = \sum_{s=1}^{t} w_s M_s$. The lower and upper confidence bounds on $\nu^{-1}$ are defined by

\[
\frac{1}{\nu t} = \min \left\{ \frac{1}{\nu t - \hat{\nu}_t + \varepsilon_t}, \frac{1}{\nu t} \right\}, \quad \bar{\nu}_t = \max \left\{ \frac{1}{\nu t - \hat{\nu}_t - \varepsilon_t}, 1 \right\} .
\]

We define $\varepsilon_t = \hat{\nu}_t^{-1} - \bar{\nu}_t^{-1}$ to be the (decreasing) width of the confidence interval. Note that both $\hat{\nu}_t$ and $\nu_t$ depend on $\delta$, although this dependence is not shown to minimise clutter.

**Theorem 3.** If $M_s$ is chosen such that $M_s \leq \nu_{s-1}$ for all $s$ then $P \{ \exists s \leq t \text{ s.t. } \nu \notin [\hat{\nu}_s, \bar{\nu}_s] \} \leq t\delta$ holds for any $0 < \delta < 1$.

**Proof of Theorem 3.** Let $F_t$ be the event $F_t = \{ \nu \in [\hat{\nu}_t, \bar{\nu}_t] \}$. Note that since $[\hat{\nu}_t, \bar{\nu}_t] \subset [\hat{\nu}_{t-1}, \bar{\nu}_{t-1}] \subset \ldots \subset [\hat{\nu}_0, \bar{\nu}_0]$, $F_t \subset F_{t-1} \subset \ldots \subset F_0$. Hence, $F_t = \cap_{s \leq t} F_s$ and it suffices to prove that $P \{ F_t \} \leq t\delta$. Define $Y_s = w_s X_s - w_s M_s$ and $S_t = \sum_{s=1}^{t} Y_s$ and $V_t^2 = \sum_{s=1}^{t} \text{Var}[Y_s | \mathcal{F}_{s-1}]$. We proceed by induction. Assume $P \{ F_{t-1} \} \leq (t-1)\delta$, which is trivial for $t = 1$. Now, on $F_{t-1}$,

\[
V_t^2 \overset{(a)}{=} \sum_{s=1}^{t} \text{Var}[Y_s | \mathcal{F}_{s-1}] \overset{(b)}{=} \sum_{s=1}^{t} \frac{w_s^2 M_s}{\nu} \left( 1 - \frac{M_s}{\nu} \right) \overset{(c)}{=} \sum_{s=1}^{t} \frac{w_s M_s}{\nu} \left( \frac{1 - M_s}{\nu} \right) \overset{(d)}{=} \sum_{s=1}^{t} \frac{w_s M_s}{\nu} \leq V_t^2 \cdot \frac{1}{2} .
\]

For an event $E$, we use $E^c$ to denote its complement.
where (a) is the definition of $V_t^2$, (b) follows since $w_t$ is $\mathcal{F}_{t-1}$-measurable, (c) follows by substituting the definition of $w_t$, (d) and (e) are true since given $F_{t-1}$ we know that $\nu - 1 \leq \nu \leq \bar{\nu}_{t-1}$. Therefore $f(R_t, V_t^2, \delta) \leq f(R_t, \hat{V}_t^2, \delta)$, which follows since $f$ is monotone increasing in its second argument. Therefore,

$$P \left\{ \frac{1}{\nu_t} - \frac{1}{\nu} \geq \hat{\epsilon}_t \wedge F_{t-1} \right\}$$

$$= P \left\{ \frac{\sum_{s=1}^t w_s X_s}{\sum_{s=1}^t w_s M_s} - \frac{1}{\nu} \geq \frac{f(R_t, \hat{V}_t^2, \delta)}{\sum_{s=1}^t w_s M_s} \wedge F_{t-1} \right\}$$

$$\leq P \left\{ \frac{\sum_{s=1}^t w_s X_s - \sum_{s=1}^t w_s M_s \nu}{\nu} \geq \frac{f(R_t, V_t^2, \delta) \wedge F_{t-1}}{\nu} \right\}$$

$$= P \left\{ |S_t| \geq f(R_t, V_t^2, \delta) \wedge F_{t-1} \right\}. \quad (2)$$

By the union bound we have

$$P \left\{ |S_t| \geq f(R_t, \hat{V}_t^2, \delta) \wedge F_{t-1}^c \right\}$$

$$\leq P \left\{ |S_t| \geq f(R_t, V_t^2, \delta) \wedge F_{t-1} \right\} + P \left\{ F_{t-1}^c \right\} \quad (a)$$

$$\leq \delta + P \left\{ F_{t-1}^c \right\} \leq \delta + (t-1)\delta = t\delta,$$

where (a) follows from a martingale version of Bernstein’s inequality adapted from Bernstein 1946 and Freedman 1975. See the supplementary material for details. Therefore $P \left\{ |S_t| \leq f(R_t, V_t^2, \delta) \wedge F_{t-1} \right\} \geq 1 - t\delta$ and so with probability at least $1 - t\delta$ we have that $F_{t-1}$ and

$$\left| \frac{1}{\nu_t} - \frac{1}{\nu} \right| \leq \frac{f(R_t, \hat{V}_t^2, \delta)}{\sum_{s=1}^t w_s M_s} = \hat{\epsilon}_t,$$

in which case

$$\frac{1}{\bar{\nu}_t} = \min \left\{ \frac{1}{\nu_t}, \frac{1}{\nu_t + \hat{\epsilon}_t} \right\} \geq \frac{1}{\nu},$$

and similarly $\frac{1}{\underline{\nu}_t} \leq \frac{1}{\nu}$, which implies $F_t$. Therefore $P \{ F_t^c \} \leq t\delta$ as required.

We now analyse the width $\epsilon_t \equiv \frac{\nu_t^{-1} - \bar{\nu}_t^{-1}}{\nu_t^{-1} - \bar{\nu}_t^{-1}}$ of the confidence interval obtained after $t$ samples are observed. We say that a job is fully allocated at time-step $s$ if $M_s = \bar{\nu}_s - 1$. The first theorem shows that the width $\epsilon_t$ drops with order $O(1/T(t))$, where $T(t) = \sum_{s=1}^t 1[M_s = \bar{\nu}_s - 1]$ is the number of fully allocated time-steps. The second theorem shows that for any $\alpha > 0$, the width $\epsilon_t$ drops with order $O(\sqrt{T(t)/\alpha U_\alpha(t)})$, where $U_\alpha(t) = \sum_{s=1}^t 1[M_s \geq \alpha]$. The dramatic difference in speeds is due to the low variance $\text{Var}[X_t|\mathcal{F}_{t-1}]$ when $M_t$ is chosen close to $\nu$. For the next results define $\eta = \min \{1, \nu \}/\nu_0$ and $\delta = \frac{\delta}{4\delta_0^2\eta^2}$.

**Theorem 4.** $\epsilon_t \leq \frac{\epsilon_1}{\nu_0(T(t) + 1)}$ where $c_1 = 27 \log^2 \frac{2}{\delta}$.

**Theorem 5.** $\epsilon_t \leq \frac{c_2}{\alpha \nu_0 U_\alpha(t)}$ where $c_2 = 6 \log^2 \frac{2}{\delta}$.

The proofs are based on the following lemma that collects some simple observations:

**Lemma 6.** The following hold for any $t \geq 1$:

1. $w_t M_t \leq \frac{1}{\epsilon_{t-1}},$ with equality if $M_s = \bar{\nu}_t - 1.$
2. $1 \leq R_t \leq \frac{1}{\nu_0 \epsilon_{t-1}}.$
3. $\epsilon_t \geq \min \{1, \nu \}.$
4. $1 - \frac{\nu_0}{\nu_t} \leq \nu_0 \epsilon_t.$

**Proof.** Using the definition of $w_t$ and the fact that $M_s$ is always chosen to be smaller or equal to $\nu_s - 1$, we get

$$w_s = \left( 1 - \frac{M_s}{\nu_s - 1} \right)^{-1} \leq \left( 1 - \frac{\nu_0}{\nu_{t-1}} \right)^{-1} = \frac{1}{\epsilon_{t-1} \nu_0 \nu_{t-1}}.$$

The first claim follows since the inequality (a) can be replaced by equality if $M_s = \nu_s - 1$. The second follows from the definition of $R_t$ and the facts that $(\epsilon_s)_s$ is non-increasing and $(\nu_s)_s$ is non-decreasing. For the third claim we recall that $R_t = \max_{s \leq t} w_s$ and $M_s \leq \nu$. Therefore,

$$\epsilon_t \geq \min \left\{ \epsilon_{t-1}, \frac{R_t}{\sum_{s=1}^t w_s M_s} \right\} \quad (a)$$

$$\geq \min \left\{ \epsilon_{t-1}, \frac{1}{t \min \{1, \nu \}} \right\}, \quad (b)$$

where (a) follows from the definition of $\epsilon_t$ and naive bounding of the function $f$, (b) follows since $R_t \geq w_s$ for all $s \leq t$ and because $M_s \leq \min \{1, \nu \}$ for all $s$. Trivial induction and the fact that $\epsilon_0 = \nu_0^{-1} \geq \nu^{-1}$ completes the proof of the third claim. For the final claim we use the facts that $\nu_0^{-1} \leq \nu^{-1} + \epsilon_t$. Therefore, $1 - \frac{\nu_0}{\nu_t} = \nu_t \left( \frac{1}{\nu_t - 1} - \frac{1}{\nu} \right) \leq \nu_t \epsilon_t$.

**Lemma 7.** $\epsilon_t \leq \frac{6 R_t \log \frac{2}{\delta}}{\sum_{s=1}^t w_s M_s} + \sqrt{\frac{8 \log \frac{2}{\delta}}{\nu_0 \sum_{s=1}^t w_s M_s}}$.

**Proof.** Let $\delta_t = \delta / (3R_t + 1)^2(\hat{V}_t^2 + 1)^2 < 1$. By the definition of $\epsilon_t$,

$$\epsilon_t \leq \frac{2 f(R_t, \hat{V}_t^2, \delta)}{\sum_{s=1}^t w_s M_s} \quad (a)$$

$$\leq \frac{4(R_t + 1)}{3} \log \frac{2}{\delta_t} + 2 \sqrt{2(\hat{V}_t^2 + 1) \log \frac{2}{\delta_t}} \quad (b)$$

$$\leq \frac{6 R_t \log \frac{2}{\delta_t}}{\sum_{s=1}^t w_s M_s} + \sqrt{\frac{8 \log \frac{2}{\delta_t}}{\nu_0 \sum_{s=1}^t w_s M_s}},$$

where in (a) we used the definition of $f$, in (b) we substituted the definition of $\hat{V}_t^2$ and used the facts that $R_t \geq 1$.
and \( \nu_0 \leq \nu_{t-1} \) and we also used a naive bound. The proof is completed by proving \( 2/\delta_t \leq 2/\delta \). Indeed, by Lemma 6, 
\[ 1 \leq R_t \leq \frac{1}{\varepsilon_t \nu_0} \leq \frac{1}{\varepsilon_t \nu_{t-1}}. \]
We also have \( V_t^2 \leq t R_t^2 \). Thus, 
\[ \frac{2}{\delta_t} = \frac{6(R_t + 1)^2(V_t^2 + 1)^2}{\delta} \leq \frac{6}{\delta} \left( 16t^2 \left( \varepsilon_t \nu_0 \right)^4 \right) \leq \frac{2}{\delta}, \]
where in (a) we used Lemma 6(3).

**Proof of Theorem 4.** By Lemma 7, 
\[ \varepsilon_t \leq \frac{6R_t \log \frac{2}{\delta}}{\sum_{s=1}^{t} \nu_s M_s} + \sqrt{\frac{8}{\nu_0 \sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta}} = \frac{6 \log \beta_t (T(t) + 1)}{2c_1}. \]
Therefore, 
\[ \sqrt{\frac{8}{\nu_0 \sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta}} \leq \frac{1}{\nu_0 T(t)} \sqrt{4c_1 \log \frac{2}{\delta}}. \]
Now we work on the first term in (3). If \( \varepsilon_{t-1} \leq \frac{\varepsilon_t}{\nu_0 (T(t) + 1)} \), then we are done, since \( \varepsilon_s \) is non-increasing. Otherwise, we use Lemma 6(2) to obtain, 
\[ \frac{6R_t}{\sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta} \leq \frac{6}{\nu_0 \varepsilon_{t-1} \sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta} \leq \frac{3}{\nu_0 T(t)} \log \frac{\beta_t}{\delta}, \]
where in (a) we used (4) and the lower bound on \( \varepsilon_{t-1} \). Substituting (5) and (6) into (3) we have 
\[ \varepsilon_t \leq \frac{1}{\nu_0 T(t)} \sqrt{4c_1 \log \frac{2}{\delta} + \frac{3}{\nu_0 T(t)} \log \frac{2}{\delta}}. \]
Choosing \( c_1 = 27 \log \frac{2}{\delta} \) leads to 
\[ \varepsilon_t \leq \frac{1}{\nu_0 T(t)} \left( 2 \sqrt{27 \log \frac{2}{\delta}} + \frac{3}{\nu_0 T(t)} \right) \log \frac{2}{\delta} \leq \frac{27}{\nu_0 T(t) + 1} \log \frac{2}{\delta} = \frac{c_1}{\nu_0 T(t) + 1}, \]
which completes the induction and proof. \( \square \)

**Proof of Theorem 5.** Firstly, by Lemma 7, 
\[ \varepsilon_t \leq \frac{6R_t}{\sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta} + \sqrt{\frac{8}{\nu_0 \sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta}}. \]
The second term is easily bounded by using the fact that \( w_s \geq 1 \) and the definition of \( U_\alpha(t) \), 
\[ \sqrt{\frac{8}{\nu_0 \sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta}} \leq \frac{\sqrt{8}}{\nu_0 U_\alpha(t)} \log \frac{2}{\delta}. \]
For the first term we assume \( \varepsilon_{t-1} \leq \frac{\varepsilon_t}{\nu_0 (T(t) + 1)} \), since otherwise we can apply monotonicity of \( \varepsilon_t \). Therefore 
\[ \frac{6R_t}{\sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta} \leq \frac{6}{\nu_0 \varepsilon_{t-1} \sum_{s=1}^{t} \nu_s M_s} \log \frac{2}{\delta} \leq \frac{U_\alpha(t) \alpha \nu_0}{c_2} \leq \frac{6}{\nu_0 U_\alpha(t)} \log \frac{2}{\delta}. \]
Now choose \( c_2 = 6 \log \frac{\sqrt{2}}{\delta} \) to complete the result. \( \square \)

## 6 PROOF OF THEOREM 2

We are now ready to use the results of Section 5 to bound the regret of Algorithm 1. The first step is to decompose the regret into two cases depending on whether or not the confidence intervals contain the truth. The probability that they do not is low, so this contributes negligibly to the regret. When the confidence intervals are valid we break the problem into two components. The first is the selection of the processes to fully allocate, which leads to the \( O(\log^2 n) \) part of the bound. The second component involves analysing the selection of the overflow process, where the approach is reminiscent of the analysis for the UCB algorithm for stochastic bandits [Auer et al., 2002].

Let \( F_{k,t} \) denote the event when none of the confidence intervals underlying job \( k \) fail up to time \( t \):
\[ F_{k,t} = \{ \forall s \leq t : \nu_s \in [\nu_{k,s}, \tilde{\nu}_{k,s}] \}. \]
The algorithm uses \( \delta = (nK)^{-2} \), which is sufficient by a union bound and Theorem 3 to ensure that,
\[ \mathbb{P}\{ G^n \} \leq \frac{1}{nK}, \quad \text{where } G = \bigcap_{k=1}^{K} F_{k,n}. \] (7)
The regret can be decomposed into two cases depending on whether \( G \) holds:
\[ R_n = \sum_{t=1}^{n} r_t \overset{(a)}{=} \mathbb{E} \sum_{t=1}^{n} r_t = \mathbb{E} \sum_{t=1}^{n} 1_{\{G^n\}} r_t + \mathbb{E} \sum_{t=1}^{n} 1_{\{\neg G^n\}} r_t \overset{(b)}{=} \mathbb{E} 1_{\{G^n\}} nK + \mathbb{E} 1_{\{\neg G^n\}} \sum_{t=1}^{n} r_t \leq 1 + \mathbb{E} 1_{\{G^n\}} \sum_{t=1}^{n} r_t, \]
where (a) follows from the definition of expectation, (b) is true by bounding \( r_t \leq K \) for all \( t \), and (c) follows from (7). For the remainder we assume \( G \) holds and use Theorems 4
and 5 combined with the definition of the algorithm to control the second term in (8). The first step is to decompose the regret in round $t$: 

$$
    r_t = \ell^* + \frac{S^*}{\nu_{t+1}} - \sum_{k=1}^K \beta \left( \frac{M_{k,t}}{\nu_k} \right).
$$

By the assumption that $G$ holds we know for all $t \leq n$ and $k$ that $\nu_{k,t-1} \leq \nu_k$, which means that $\beta(M_{k,t}/\nu_k) = M_{k,t}/\nu_k$. Define $\pi_i(t) \in \{1, \ldots, K\}$ such that $\nu_{\pi_i(t),t-1} \leq \nu_{\pi_i(t)+1,t-1}$. Also let

- $A_t = \{k : M_{k,t} = \nu_k\}$,
- $A_{t}^{<j} = A_t \cap \{\pi_i(t) : 1 \leq i \leq j\}$,
- $T_k(t) = \sum_{s=1}^t 1\{k \in A_t\}$ and $B_t = \pi_t(\ell + 1)$.

Informally, $A_t$ is the set of jobs that are fully allocated at time-step $t$, $A_{t}^{<j}$ is a subset of $A_t$ containing the $j$ jobs believed to be easiest, $T_k(t)$ is the number of times job $k$ has been fully allocated at time-step $t$, and $B_t$ is the $(\ell + 1)$th easiest job at time-step $t$ (this is only defined if $\ell < K$ and will only be used in that case).

**Lemma 8.** For all $t$, $|A_t| \geq \ell$ and if $|A_t| = \ell$, then $M_{B_t,t} \geq S^*$.

**Proof.** $|A_t| = \max\left\{ j : \sum_{i=1}^j \nu_{\pi_i(t),t-1} \leq 1 \right\}$. But $\sum_{k=1}^t \nu_{k,t-1} \leq \nu_k$ for all $k$ and $t$, so $\sum_{i=1}^\ell \nu_{\pi_i(t),t-1} \leq \sum_{k=1}^t \nu_k \leq 1$. Therefore $|A_t| \geq \ell$. If $|A_t| = \ell$, then $B_t \notin A_t$ is the overflow job and so $M_{B_t,t} = 1 - \sum_{k \in A_t} \nu_{k,t-1} \geq 1 - \sum_{k \in A*} \nu_{k,t-1} \geq 1 - \sum_{k \in A*} \nu_k$.

We now decompose the regret, while still assuming that $G$ holds:

$$
    \sum_{t=1}^n r_t = \sum_{t=1}^n \left( \ell + \frac{S^*}{\nu_{t+1}} - \sum_{k=1}^K \frac{M_{k,t}}{\nu_k} \right) 
    \leq \sum_{t=1}^n \sum_{k \in A_{t}^{<\ell}} \left( 1 - \frac{M_{k,t}}{\nu_k} \right) 
    + 1\{\ell < K\} \sum_{t=1}^n \left( \frac{S^*}{\nu_{t+1}} - \frac{M_{B_t,t}}{\nu_{B_t}} \right). \quad (9)
$$

Let us bound the first sum:

$$
    \sum_{t=1}^n \sum_{k \in A_{t}^{<\ell}} \left( 1 - \frac{M_{k,t}}{\nu_k} \right) 
    = \sum_{t=1}^n \sum_{k=1}^K 1\{k \in A_{t}^{<\ell}\} \left( 1 - \frac{\nu_{k,t-1}}{\nu_k} \right) 
    \leq \sum_{t=1}^n 1\{k \in A_{t}^{<\ell}\} \frac{\nu_{k,t-1}}{\nu_k}. \quad (10)
$$

Continuing (11) by applying Lemma 9 with $j = \ell$:

$$
    \sum_{t=1}^n \sum_{k=1}^K 1\{k \in A_{t}^{<\ell}\} \frac{c_k \nu_{k,t-1}}{\nu_k \nu_{k,0} T_k(t)} 
    = \sum_{t=1}^n \sum_{k \in A*} 1\{k \in A_{t}^{<\ell}\} \frac{c_k \nu_{k,t-1}}{\nu_k \nu_{k,0} T_k(t)} 
    + \sum_{t=1}^n \sum_{k \notin A*} 1\{k \in A_{t}^{<\ell}\} \frac{c_k \nu_{k,t-1}}{\nu_k \nu_{k,0} T_k(t)} \quad (12)
$$

where (a) follows from Lemma 9 and the fact that $k \in A_{t}^{<\ell}$ implies that $c_k \nu_{k,t-1} \leq \nu_k$. Now if $\ell = K$, then the second term in (10) is zero and the proof is completed by substituting the above result into (9) and then into (8). So now we assume $\ell > K$ and bound the second term in (9) as follows:

$$
    \sum_{t=1}^n \sum_{k \notin A*} 1\{k \in A_{t}^{<\ell}\} \left( \frac{S^*}{\nu_{t+1}} - \frac{S^*}{\nu_{B_t}} \right) 
    \leq \sum_{t=1}^n 1\{B_t \in A_t\} \left( 1 - \frac{\nu_{B,t-1}}{\nu_{B_t}} \right) 
    + \sum_{t=1}^n 1\{B_t \notin A_t\} \left( \frac{S^*}{\nu_{t+1}} - \frac{S^*}{\nu_{B_t}} \right), \quad (13)
$$
where we used Lemma 8 and $S^* \leq 1$ and that if $B_t \in A_t$, then $M_{B_t,t} = \nu B_{t-1}$. Bounding each term separately:

$$\sum_{t=1}^n \mathbb{I}\{B_t \in A_t\} \left( 1 - \frac{\nu B_{t-1}}{\nu B_t} \right)$$

\(\leq\)

$$\sum_{k=1}^K \sum_{t=1}^n \mathbb{I}\{k \in A_t^{\leq \ell+1}\} \left( 1 - \frac{\nu_{k,t-1}}{\nu_k} \right)$$

\(\leq\)

$$K \sum_{k=1}^n \mathbb{I}\{k \in A_t^{\leq \ell+1}\} \nu_{k,t-1} \Delta_{k,t-1}$$

\(=\)

$$K \sum_{k=1}^n \mathbb{I}\{k \in A_t^{\leq \ell+1}\} \frac{\nu_{k,t-1} \Delta_{k,t-1}}{\nu_k}$$

where (a) follows from the definition of $\Delta_{t+1,k}$ and the fact that if $B_t \notin A_t$, then $|A_t| = \ell$, (b) follows since $\Delta_{t+1,k}$ is negative for $k \leq \ell + 1$, (c) by Lemma 8, (d) by Lemma 10, and (e) by the definition of $\nu_k$. Substituting (14) and (15) into (13) we have

$$\sum_{t=1}^n \left( \frac{S^*}{\nu + 1} - \frac{M_{B_t,t}}{\nu B_t} \right) \leq \sum_{k=1}^{\ell+1} c_k, \nu_k(1 + \log n)$$

$$+ \sum_{k=\ell+2}^K c_k, \nu_k(1 + \log u_{\ell+1,k}) + \sum_{k=\ell+2}^K \frac{c_k,2}{\nu_k,0 \Delta_{t+1,k}}.$$
implementations of Algorithm 2. For job $k$, start Algorithm 2 in time-step $k$, which means that the total amount of resources used by the parallel copies of Algorithm 2 in time-step $t$ is bounded by

$$
\sum_{k=1}^{K} I\{t \geq k\} 2^{k-t-1}
\leq \min \{1, 2^{K-t}\}.
$$

Algorithm 1 is implemented starting from time-step 1, but only allocates resources to jobs for which the initialisation process has completed. Estimates are computed using only the samples for which Algorithm 1 chose the allocation, which ensures that they are based on allocations with $M_{k,t} \leq \nu_k$. Note that the analysis of the modified algorithm does not depend on the order in which the parallel processes are initialised. The regret incurred by the modified algorithm is given in order notation in (1). The proof is omitted, but relies on two observations. First, that the expected number of time-steps that a job is not (at least) fully allocated while it is being initialised is 2. The second is that the resources available to Algorithm 1 at time-step $t$ converges exponentially fast to 1 by (16).

8 MINIMAX LOWER BOUNDS

Despite the continuous action space, the techniques used when proving minimax lower bounds for standard stochastic bandits [Auer et al., 1995] can be adapted to our setting. The proof is included in the supplementary material.

**Theorem 12.** Given fixed $n$ and $8n \geq K \geq 2$ and an arbitrary algorithm, there exists an allocation problem for which the expected regret satisfies $R_n \geq \sqrt{\frac{2nK}{10\nu^2}}$.

9 EXPERIMENTS

All code and data is available in the supplementary material. Data points were generated using the modified algorithm described in Section 7 and by taking the mean of 300 samples. With this many samples the standard error is relatively low (and omitted for readability). We should note that the variance in the regret of the modified algorithm is extremely low. To illustrate the behaviour of the algorithm we performed four experiments on synthetic data with $K = 2$, which are plotted below as TL (top left), TR, BL, BR (bottom right) respectively. In TL we fixed $n = 10^4$, $\nu_1 = 2$ and plotted the regret as a function of $\nu_2 \in [2, 10]$. The experiment shows the usual bandit-like dependence on the gap $1/\Delta_{1.2}$. In TR we fixed $\nu_1 = 4/10$, $\nu_2 = 6/10$ and plotted $R_n/\log^2 n$ as a function of $n$. The experiment lies within case 2 described in Section 4 and shows that the algorithm suffers regret $R_n \approx 45\log^2 n$ as predicted by Theorem 2. In BL we fixed $n = 10^2$, $\nu_1 = 4/10$ and plotted the regret as a function of $\nu_2 \in [4/10, 1]$. The results show the algorithm suffering $O(\log^2 n)$ regret for both processes until the critical point when $\nu_2 > 6/10$ when the second process can no longer be fully allocated, which is quickly learned and the algorithm suffers $O(\log^2 n)$ regret for only one process. In BR we fixed $\nu_1 = 4/10$ and $\nu_2 = 6/10$ and plotted the regret as a function of $n$ for two algorithms. The first algorithm (solid blue) is the modified version of Algorithm 1 as described in Section 7. The second (dotted red) is the same, but uses the unweighted estimator $w_{k,t} = 1$ for all $k$ and $t$. The result shows that both algorithms suffer sub-linear regret, but that the weighted estimator is a significant improvement over the unweighted one.

10 CONCLUSIONS

We introduced the linear stochastic resource allocation problem and a new optimistic algorithm for this setting. Our main result shows that the new algorithm enjoys a (squared) logarithmic problem-dependent regret. We also presented a minimax lower bound of $\Omega(\sqrt{nK})$, which is consistent with the problem-dependent upper bound. The simulations confirm the theory and highlight the practical behaviour of the new algorithm. There are many open questions and possibilities for future research. Most important is whether the $\log^2 n$ can be reduced to $\log n$. Problem-dependent lower bounds would be interesting. The algorithm is not anytime (although a doubling trick presumably works in theory). Developing and analysing algorithms when the horizon it not known, and have high-probability bounds are both of interest. We also wonder if Thompson sampling can be efficiently implemented for some reasonable prior, and if it enjoys the same practical and theoretical guarantees in this domain as it does for bandits. Other interesting extensions are when resources are not replenished, or the state of the jobs follow a Markov process. Finally, we want to emphasise that we have made just the first steps towards developing this new and interesting setting. We hope to see significant activity extending and modifying the model/algorithm for specific problems.
