

## A Proof of Proposition 1

**Proposition 2.** For any  $\pi$  on  $\Omega$  as in (1), and any  $\epsilon > 0$ , there are positive constants  $w_i = w_i(\epsilon) > 0$ , and normalized modular functions  $m_i = m_i(\epsilon)$ ,  $i \in \{1, \dots, r\}$ , such that, if we define  $q(S) := \sum_{i=1}^r w_i \exp(m_i(S))$ , for all  $S \in \Omega$ , then  $d_{TV}(\pi, q) \leq \epsilon$ .

*Proof.* Let  $r = |\Omega|$ , and let  $(S_i)_{i=1}^r$  be an enumeration of all sets in  $\Omega$ . For any  $i \in \{1, \dots, r\}$ , and any  $v \in V$ , we define

$$m_{iv} = \begin{cases} \beta_i, & \text{if } v \in S_i \\ -\beta_i, & \text{otherwise} \end{cases},$$

and  $m_i(S) = \sum_{v \in S} m_{iv}$ , for all  $S \in \Omega$ . We also define

$$w_i = \frac{\pi(S_i)}{Z_i} = \frac{\pi(S_i)}{(1 + e^{\beta_i})^{|S_i|} (1 + e^{-\beta_i})^{|V \setminus S_i|}}.$$

Then, for all  $i \in \{1, \dots, r\}$ , we have

$$\begin{aligned} d_i(\beta_1, \dots, \beta_r) &:= |\pi(S_i) - q(S_i)| \\ &= \left| \pi(S_i) - \sum_{j=1}^r \pi(S_j) \frac{e^{\beta_j |S_j|}}{(1 + e^{\beta_j |S_j|}) (1 + e^{-\beta_j |V \setminus S_j|})} \right| \\ &\leq \pi(S_i) \left( 1 - \frac{e^{\beta_i |S_i|}}{(1 + e^{\beta_i |S_i|}) (1 + e^{-\beta_i |V \setminus S_i|})} \right) + \\ &\quad \sum_{j: S_j \neq S_i} \pi(S_j) \frac{e^{\beta_j |S_j|}}{(1 + e^{\beta_j |S_j|}) (1 + e^{-\beta_j |V \setminus S_j|})}. \end{aligned}$$

Note that both terms vanish if we let all  $\beta_j \rightarrow \infty$ . Therefore, for any  $\delta > 0$ , there are  $\beta_{ij} = \beta_{ij}(\delta)$ , for all  $j \in \{1, \dots, r\}$ , such that  $d_i(\beta_{i1}, \dots, \beta_{ir}) \leq \delta$ .

Finally, choosing  $\hat{\beta}_j := \max_{i \in \{1, \dots, r\}} \beta_{ij}$ , for all  $j \in \{1, \dots, r\}$ , we get

$$d_{TV}(\pi, q) = \frac{1}{2} \sum_{i=0}^r d_i(\hat{\beta}_1, \dots, \hat{\beta}_r) \leq 2^{n-1} \delta.$$

The result follows by choosing  $\delta = \epsilon/2^{n-1}$ .  $\square$

## B Ising Model on the Complete Graph

### B.1 Bounds on Gibbs mixing

**Theorem B1** (Theorem 15.3 in (Levin et al., 2008b)). If  $\beta > 1$ , then the Gibbs sampler on ISING $_\beta$  has a bottleneck ratio  $\Phi_* = \mathcal{O}(e^{-c(\beta)n})$ , where  $c(\beta)$  is a non-decreasing function of  $\beta$ .

**Corollary 1** (cf. Theorem 15.3 in (Levin et al., 2008b)). For  $n \geq 3$ , the Gibbs sampler on ISING has spectral gap  $\gamma^G = \mathcal{O}(e^{-cn})$ , where  $c > 0$  is a constant.

**Corollary 2** (cf. Theorem 2 in (Ding et al., 2009)). For all  $n \geq 3$ , the restriction chains  $P_i^G$ ,  $i = 0, 1$ , of the Gibbs sampler on ISING have spectral gap  $\gamma_i^G = \Theta\left(\frac{2 \ln(n) - 1}{n}\right)$ .

### B.2 Bounds on M<sup>3</sup> mixing

**M<sup>3</sup> sampler.** The proposal distribution can be written as follows,

$$q(S) = \frac{1}{2} \left( \frac{\exp(-d_n(n-1)|S|)}{Z_1} + \frac{\exp(d_n(n-1)|S|)}{Z_2} \right), \quad (4)$$

where  $Z_1 = (1 + \exp(-d_n(n-1)))^n$ , and  $Z_2 = (1 + \exp(d_n(n-1)))^n$ .

**Lemma B1** (Fact 6 in (Anari et al., 2016)). The spectral gap of any reversible two-state chain  $P$  with stationary distribution  $\pi$  that satisfies  $P(0, 1) = c\pi(1)$  is  $c$ .

**Lemma 1.** For all  $n \geq 10$ , the projection chain  $\bar{P}^M$  of the M<sup>3</sup> sampler on ISING has spectral gap  $\bar{\gamma}^M = \Omega(1)$ .

*Proof.* We define  $\pi_k = \sum_{S \in \Omega, |S|=k} \pi(S)$ , and  $q_k = \sum_{S \in \Omega, |S|=k} q(S)$ .

**Bounding  $\pi_k$ .** By definition, we can write  $\pi_k = \hat{\pi}_k/Z$ , where  $\hat{\pi}_0 = 1$ , and for  $k > 0$  we have

$$\begin{aligned} \hat{\pi}_k &:= \binom{n}{k} \exp\left(-\frac{2 \ln(n)}{n} k(n-k)\right) \\ &= \binom{n}{k} n^{-\frac{2k}{n}(n-k)} \\ &\leq \left(\frac{en}{k}\right)^k n^{-\frac{2k}{n}(n-k)} \\ &= \left(\frac{e}{k}\right)^k n^{-k + \frac{2k^2}{n}}. \end{aligned}$$

It follows that

$$\ln(\hat{\pi}_k) \leq -k \ln\left(\frac{k}{e}\right) + \left(\frac{2k^2}{n} - k\right) \ln(n). \quad (5)$$

It is easy to verify that for all  $n \geq 10$  and  $3 \leq k \leq \lfloor n/2 \rfloor$ , it holds that  $(2k-n) \ln(n) \leq 0.5n \ln(k/e)$ . Substituting this into (5), we get

$$\begin{aligned} \ln(\hat{\pi}_k) &\leq -0.5k \ln\left(\frac{k}{e}\right) \\ \Rightarrow \hat{\pi}_k &\leq \exp(-0.5k \ln(k/e)). \end{aligned}$$

Noting that, for all  $k$ ,  $\hat{\pi}_k \leq 1$ , and using the fact that  $\hat{\pi}_{n-k} = \hat{\pi}_k$ , we get

$$\begin{aligned}
Z &= \sum_{k=0}^n \hat{\pi}_k \\
&\leq 2 \sum_{k=0}^{\lfloor n/2 \rfloor} \hat{\pi}_k \\
&= 2(\hat{\pi}_0 + \hat{\pi}_1 + \hat{\pi}_2 + \sum_{k=3}^{\lfloor n/2 \rfloor} \hat{\pi}_k) \\
&\leq 3 + \sum_{k=3}^{\lfloor n/2 \rfloor} \exp(-0.5k \ln(k/e)) \\
&\leq c_1,
\end{aligned} \tag{6}$$

where  $c_1$  is a constant.

**Bounding  $q_k$ .** First, it is easy to see that, for all  $n \geq 1$ ,  $Z_1 \leq 3$ .

$$\begin{aligned}
q_k &= \sum_{S \in \Omega, |S|=k} q(S) \\
&\geq \sum_{S \in \Omega, |S|=k} \frac{1}{2} \frac{\exp(-d_n(n-1)|S|)}{Z_1} \quad (\text{by (4)}) \\
&\geq \frac{1}{6} \binom{n}{k} \exp(-d_n(n-1)|S|)
\end{aligned}$$

**Bounding the spectral gap.** For the projection chain  $\bar{P}^M$ , we have

$$\begin{aligned}
\bar{P}^M(0, 1) &= \frac{1}{\bar{\pi}(0)} \sum_{\substack{S \in \Omega_i \\ R \in \Omega_j}} \pi(S) P^M(S, R) \\
&\geq 2\pi_0 q_n \quad (\bar{\pi}(0) = 1/2 \text{ by symmetry of } \pi) \\
&= 2\pi_0 q_0 \quad (\text{by symmetry of } q) \\
&\geq 2 \frac{\hat{\pi}_0}{Z} \frac{1}{6} \quad (q_0 \geq \frac{1}{6}) \\
&\geq 2 \frac{1}{c_1} \frac{1}{6} \quad (\hat{\pi}_0 = 1) \\
&= c\bar{\pi}(1),
\end{aligned}$$

where  $c = (2/3)c_1$ .

Finally, it follows from [Lemma B1](#) that the spectral gap of  $\bar{P}^M$  is  $c$ .  $\square$

### B.3 Bounds on combined sampler mixing

**Lemma B2.** For all  $n \geq 10$ , the projection chain  $\bar{P}^C$  of the combined chain on ISING has spectral gap  $\bar{\gamma}^C = \Omega(1)$ .

*Proof.* By definition,  $\bar{P}^C(S, R) \geq \alpha \bar{P}^M(S, R)$ , therefore a simple comparison argument (e.g., Lemma 13.22 in [\(Levin et al., 2008b\)](#)) combined with the result of [Lemma 1](#) gives us  $\bar{\gamma}^C \geq \alpha \bar{\gamma}^M = \Omega(1)$ .  $\square$

**Lemma B3.** For all  $n \geq 3$ , each of the restriction chains  $P_i^C$  of the combined chain on ISING has spectral gap  $\gamma_i^C = \Theta\left(\frac{2 \ln(n) - 1}{2n}\right)$ .

*Proof.* By definition,  $P_i^C(S, R) \geq \alpha P_i^G(S, R)$ , therefore, using a comparison argument like above together with [Lemma 2](#) gives us  $\gamma_i^C \geq \alpha \gamma_i^G = \Theta\left(\frac{2 \ln(n) - 1}{2n}\right)$ .  $\square$

**Theorem B2** (Theorem 1 in [\(Jerrum et al., 2004\)](#)). Given a reversible Markov chain  $P$ , if the spectral gap of its projection chain  $\bar{P}$  is bounded below by  $\bar{\gamma}$ , and the spectral gaps of its restriction chains  $P_i$  are uniformly bounded below by  $\gamma_{\min}$ , then the spectral gap of  $P$  is bounded below by

$$\gamma = \min \left\{ \frac{\bar{\gamma}}{3}, \frac{\bar{\gamma} \gamma_{\min}}{3P_{\max} + \bar{\gamma}} \right\},$$

where  $p_{\max} := \max_{i \in \{0,1\}} \max_{S \in \Omega_i} \sum_{R \in \Omega \setminus \Omega_i} P(S, R)$ .

**Theorem 2.** For all  $n \geq 10$ , the combined chain  $P^C$  on ISING has spectral gap

$$\gamma^C = \Omega\left(\frac{2 \ln(n) - 1}{2n}\right).$$

*Proof.* The result follows directly by combining the spectral gap bounds of [Lemmas B2](#) and [B3](#) in [Theorem B2](#), and noting that  $P_{\max} \leq 1$ .  $\square$
